**On the Cover:** In common with land plants, homogalacturonans (HGs) constitute a major fraction of the cell wall of the Charophycean green alga *Penium margaritaceum*. These pectin macromolecules form the fibrillar outer layer that anchors into the inner cellulose-rich stratum (background image). HG secretion during cell development may be monitored in live cells labeled with anti-HG monoclonal antibodies (e.g. LM18, JIM5). In LM18-labeled cells (center, top), the HGs of older cell wall regions are displaced outward toward the polar zones. JIM5-labeled cells treated for 24 h with 0.28  $\mu\text{M}$  of the microtubule inhibitor oryzalin show distinct swelling of the cell center and alteration of HG microarchitecture. Sørensen et al. (pp. 366–372) analyze cell wall macromolecule distribution and evolutionary trends in primitive land plants and their ancestral stock, the Charophycean green algae. *Penium* represents a unicellular model charophyte that provides important insight into cell wall dynamics and evolution. Microscopic imaging and cover design by David Domozych.

## FOCUS ISSUE ON PLANT CELL WALLS

### EDITORIAL

Blueprints for Building Plant Cell Walls. *Maureen McCann and Jocelyn Rose* 365

### UPDATES

How Have Plant Cell Walls Evolved? *Iben Sørensen, David Domozych, and William G.T. Willats* 366

Beyond the Green: Understanding the Evolutionary Puzzle of Plant and Algal Cell Walls. *Zoë A. Popper and Maria G. Tuohy* 373

Biosynthesis of Pectin. *Jesper Harholt, Anongpat Suttangkakul, and Henrik Vibe Scheller* 384

Xylan Biosynthesis: News from the Grass. *Ahmed Faik* 396
